

## MDPs: overview

## Markov decision process

#### Definition: Markov decision process-

```
States: the set of states
```

```
s_{\text{start}} \in \text{States: starting state}
```

```
Actions(s): possible actions from state s
```

```
T(s, a, s'): probability of s' if take action a in state s
```

```
Reward(s, a, s'): reward for the transition (s, a, s')
```

```
IsEnd(s): whether at end of game
```

```
0 \leq \gamma \leq 1: discount factor (default: 1)
```

## What is a solution?

Search problem: path (sequence of actions)

MDP:

#### **Definition: policy-**

A **policy**  $\pi$  is a mapping from each state  $s \in \text{States to an action } a \in \text{Actions}(s)$ .

Γ	Example:	volcano	crossing-
	s	$\pi(s)$	
	(1,1)	S	
	(2,1)	E	
	(3,1)	Ν	

# MDPs: policy evaluation

# Discounting

- Characteria -

Path:  $s_0, a_1r_1s_1, a_2r_2s_2, \ldots$  (action, reward, new state). The **utility** with discount  $\gamma$  is  $u_1 = r_1 + \gamma r_2 + \gamma^2 r_3 + \gamma^3 r_4 + \cdots$ 

Discount  $\gamma = 1$  (save for the future):

[stay, stay, stay, stay]: 4 + 4 + 4 = 16

Discount  $\gamma = 0$  (live in the moment):

[stay, stay, stay, stay]:  $4 + 0 \cdot (4 + \cdots) = 4$ 

Discount  $\gamma = 0.5$  (balanced life):

[stay, stay, stay, stay]:  $4 + \frac{1}{2} \cdot 4 + \frac{1}{4} \cdot 4 + \frac{1}{8} \cdot 4 = 7.5$ 

## Policy evaluation

#### Definition: value of a policy-

Let  $V_{\pi}(s)$  be the expected utility received by following policy  $\pi$  from state s.

#### Definition: Q-value of a policy-

Let  $Q_{\pi}(s, a)$  be the expected utility of taking action a from state s, and then following policy  $\pi$ .

## Policy evaluation

Plan: define recurrences relating value and Q-value

## Policy evaluation

Start with arbitrary policy values and repeatedly apply recurrences to converge to true values.

Algorithm: policy evaluation Initialize  $V_{\pi}^{(0)}(s) \leftarrow 0$  for all states s. For iteration  $t = 1, \dots, t_{\mathsf{PE}}$ : For each state s:  $V_{\pi}^{(t)}(s) \leftarrow \sum_{s'} T(s'|s, \pi(s))[\mathsf{Reward}(s, \pi(s), s') + \gamma V_{\pi}^{(t-1)}(s')]$  $Q^{(t-1)}(s, \pi(s))$ 

![](_page_8_Picture_0.jpeg)

## MDPs: value iteration

![](_page_8_Picture_2.jpeg)

## Optimal value and policy

Goal: try to get directly at maximum expected utility

![](_page_9_Picture_2.jpeg)

The **optimal value**  $V_{opt}(s)$  is the maximum value attained by any policy.

### Optimal values and Q-values

![](_page_10_Figure_1.jpeg)

Optimal value if take action a in state s:

$$Q_{\mathsf{opt}}(s, a) = \sum_{s'} T(s, a, s') [\mathsf{Reward}(s, a, s') + \gamma V_{\mathsf{opt}}(s')].$$

Optimal value from state s:

$$V_{\mathsf{opt}}(s) = \begin{cases} 0 & \text{if } \mathsf{IsEnd}(s) \\ \max_{a \in \mathsf{Actions}(s)} Q_{\mathsf{opt}}(s, a) & \text{otherwise.} \end{cases}$$

## **Optimal policies**

![](_page_11_Figure_1.jpeg)

Given  $Q_{opt}$ , read off the optimal policy:

$$\pi_{\mathsf{opt}}(s) = \arg \max_{a \in \mathsf{Actions}(s)} Q_{\mathsf{opt}}(s, a)$$

## Value iteration

![](_page_12_Figure_1.jpeg)

Time:  $O(t_{VI}SAS')$ 

![](_page_13_Picture_0.jpeg)

![](_page_13_Picture_1.jpeg)

![](_page_13_Picture_2.jpeg)

## Summary of algorithms

• Policy evaluation: (MDP,  $\pi$ )  $\rightarrow V_{\pi}$ 

• Value iteration:  $MDP \rightarrow (Q_{opt}, \pi_{opt})$ 

![](_page_15_Picture_0.jpeg)

# MDPs: reinforcement learning

![](_page_15_Picture_2.jpeg)

## Unknown transitions and rewards

![](_page_16_Picture_1.jpeg)

Definition: Markov decision process-

States: the set of states

 $s_{\mathsf{start}} \in \mathsf{States:} \ \mathsf{starting} \ \mathsf{state}$ 

Actions(s): possible actions from state s

IsEnd(s): whether at end of game  $0 \le \gamma \le 1$ : discount factor (default: 1)

reinforcement learning!

![](_page_17_Picture_0.jpeg)

## MDPs: model-based methods

![](_page_17_Picture_2.jpeg)

#### Model-Based Value Iteration

Data:  $s_0; a_1, r_1, s_1; a_2, r_2, s_2; a_3, r_3, s_3; \ldots; a_n, r_n, s_n$ 

Fig. Key idea: model-based learning Estimate the MDP: T(s, a, s') and Reward(s, a, s')

Transitions:

$$\hat{T}(s, a, s') = \frac{\# \operatorname{times} (s, a, s') \operatorname{occurs}}{\# \operatorname{times} (s, a) \operatorname{occurs}}$$

Rewards:

$$\widehat{\mathsf{Reward}}(s, a, s') = r \text{ in } (s, a, r, s')$$

### Model-Based Value Iteration

![](_page_19_Figure_1.jpeg)

Data (following policy  $\pi(s) = \text{stay}$ ):

[in; stay, 4, end]

- Estimates converge to true values (under certain conditions)
- With estimated MDP  $(\hat{T}, \widehat{\text{Reward}})$ , compute policy using value iteration

## Problem

![](_page_20_Figure_1.jpeg)

Problem: won't even see (s, a) if  $a \neq \pi(s)$  (a = quit)

![](_page_20_Figure_3.jpeg)

Solution: need  $\pi$  to explore explicitly (more on this later)

![](_page_21_Picture_0.jpeg)

## MDPs: model-free methods

![](_page_21_Picture_2.jpeg)

### From model-based to model-free

$$\hat{Q}_{\mathsf{opt}}(s,a) = \sum_{s'} \hat{T}(s,a,s') [\widehat{\mathsf{Reward}}(s,a,s') + \gamma \hat{V}_{\mathsf{opt}}(s')]$$

All that matters for prediction is (estimate of)  $Q_{opt}(s, a)$ .

**Key idea: model-free learning**  
Try to estimate 
$$Q_{opt}(s, a)$$
 directly.

## Model-free Monte Carlo

Data (following policy  $\pi$ ):

```
s_0; a_1, r_1, s_1; a_2, r_2, s_2; a_3, r_3, s_3; \ldots; a_n, r_n, s_n
```

Recall:

 $Q_{\pi}(s, a)$  is expected utility starting at s, first taking action a, and then following policy  $\pi$ Utility:

$$u_t = r_t + \gamma \cdot r_{t+1} + \gamma^2 \cdot r_{t+2} + \cdots$$

Estimate:

$$\hat{Q}_{\pi}(s,a) = \mathsf{average} \,\, \mathsf{of} \,\, u_t \,\, \mathsf{where} \,\, s_{t-1} = s, a_t = a$$

(and s, a doesn't occur in  $s_0, \dots, s_{t-2}$ )

### Model-free Monte Carlo

![](_page_24_Figure_1.jpeg)

Data (following policy  $\pi(s) = \text{stay}$ ):

[in; stay, 4, in; stay, 4, in; stay, 4, in; stay, 4, end]

Note: we are estimating  $Q_{\pi}$  now, not  $Q_{\text{opt}}$ 

#### Definition: on-policy versus off-policy-

On-policy: estimate the value of data-generating policy Off-policy: estimate the value of another policy

![](_page_25_Picture_0.jpeg)

## MDPs: SARSA

![](_page_25_Picture_2.jpeg)

### Using the reward + Q-value

Current estimate:  $\hat{Q}_{\pi}(s, \text{stay}) = 11$ Data (following policy  $\pi(s) = \text{stay}$ ): [in; stay, 4, end] 4 + 0[in; stay, 4, in; stay, 4, end] 4 + 11[in; stay, 4, in; stay, 4, in; stay, 4, end] 4 + 11[in; stay, 4, in; stay, 4, in; stay, 4, in; stay, 4, end] 4 + 11**Algorithm: SARSA-**On each (s, a, r, s', a').

$$\hat{Q}_{\pi}(s,a) \leftarrow (1-\eta)\hat{Q}_{\pi}(s,a) + \eta[\underbrace{r}_{\text{data}} + \gamma \underbrace{\hat{Q}_{\pi}(s',a')}_{\text{data}}]$$

estimate

### Model-free Monte Carlo versus SARSA

SARSA uses estimate  $\hat{Q}_{\pi}(s, a)$  instead of just raw data u.

 $\mathcal{U}$ 

 $r + \hat{Q}_{\pi}(s', a')$ 

based on one pathbasedunbiasedbiasedlarge variancesmalwait until end to updatecan update

based on estimate biased small variance can update immediately

![](_page_28_Picture_0.jpeg)

# MDPs: Q-learning

![](_page_28_Picture_2.jpeg)

# Q-learning

**Problem**: model-free Monte Carlo and SARSA only estimate  $Q_{\pi}$ , but want  $Q_{opt}$  to act optimally

Output	MDP	reinforcement learning
$Q_{\pi}$	policy evaluation	model-free Monte Carlo, SARSA
$Q_{opt}$	value iteration	Q-learning

# Q-learning

Bellman optimality equation:

$$Q_{\mathsf{opt}}(s, a) = \sum_{s'} T(s, a, s') [\mathsf{Reward}(s, a, s') + \gamma V_{\mathsf{opt}}(s')]$$

![](_page_30_Figure_3.jpeg)

## Off-Policy versus On-Policy

#### Definition: on-policy versus off-policy-

On-policy: evaluate or improve the data-generating policy Off-policy: evaluate or learn using data from another policy

#### on-policy off-policy

policy evaluation Monte Carlo SARSA

policy optimization

Q-learning

## Reinforcement Learning Algorithms

Algorithm	Estimating	Based on
Model-Based Monte Carlo	$\hat{T},\hat{R}$	$s_0, a_1, r_1, s_1, \dots$
Model-Free Monte Carlo	$\hat{Q}_{\pi}$	u
SARSA	$\hat{Q}_{\pi}$	$r + \hat{Q}_{\pi}$
Q-Learning	$\hat{Q}_{\sf opt}$	$r + \hat{Q}_{opt}$
